1 Validation Case 24 - Flexible pendulum

Model Description

This test case is based on the example "A flexible pendulum" described in Ref. [1] and Ref. [2].

A simple beam is placed initially in vertical position, and an angular velocity $\omega_0 = 2 \text{ rad/s}$ is consistently applied to all nodes. The pendulum's tip is subjected to a constant force $F = 8 \text{ N}$, and no body forces are considered. The following image shows the geometry:

The pendulum section has the following properties (the material is assumed to be linear elastic):

$$E \cdot A = 50.68e5 \text{ N}$$

$$\kappa \cdot G \cdot A = 25.34e5 \text{ N}$$

$$E \cdot I = 570.37 \text{ N} \cdot \text{m}^2$$

$$A_p = 20.34e-2 \text{ kg/m}$$

$$I_p = 22.89e-6 \text{ kg} \cdot \text{m}$$

Results

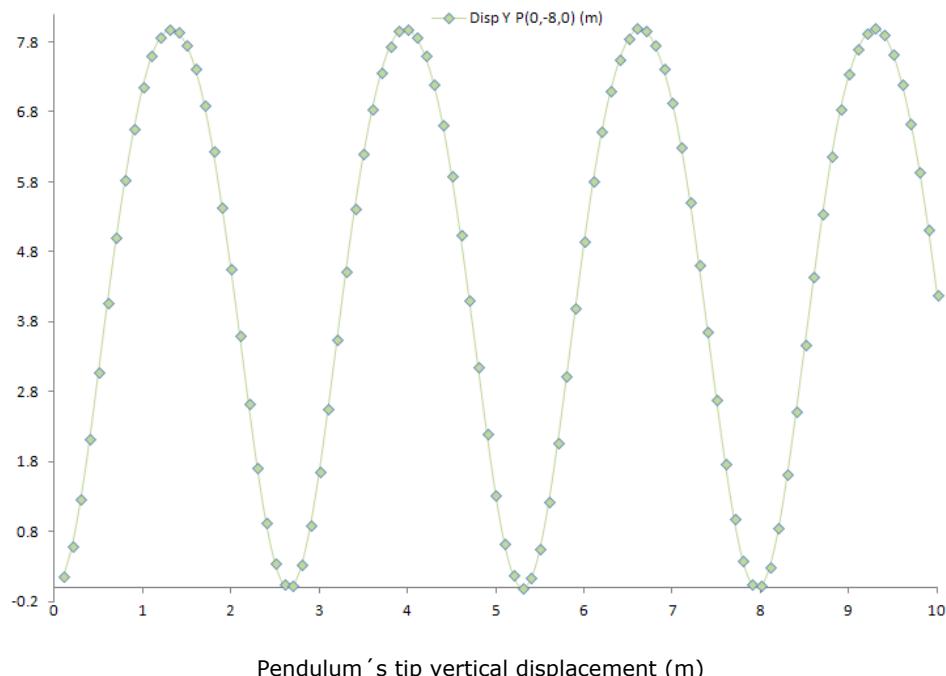

For the sake of validation, a simulation was run using the properties described in the previous section, using a four linear beam element (5 nodes) mesh.

The total time of the simulation is $T=10$ s, with a time step of $\Delta t = 0.1$ s.

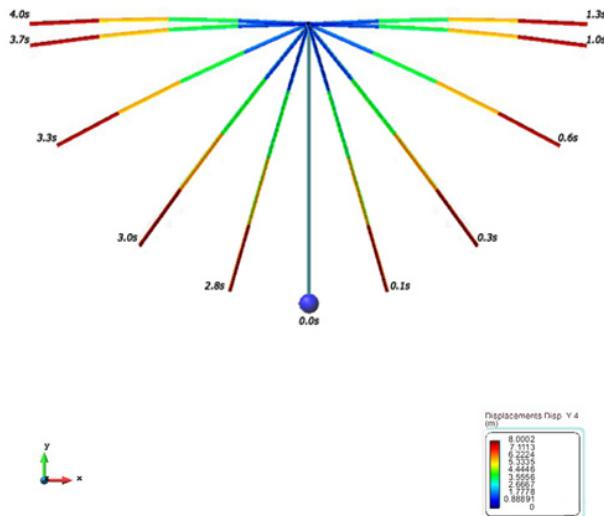

An implicit energy-conserving scheme is used.

Displacements results:

The next image shows the vertical displacement evolution of the lowest point of the pendulum:

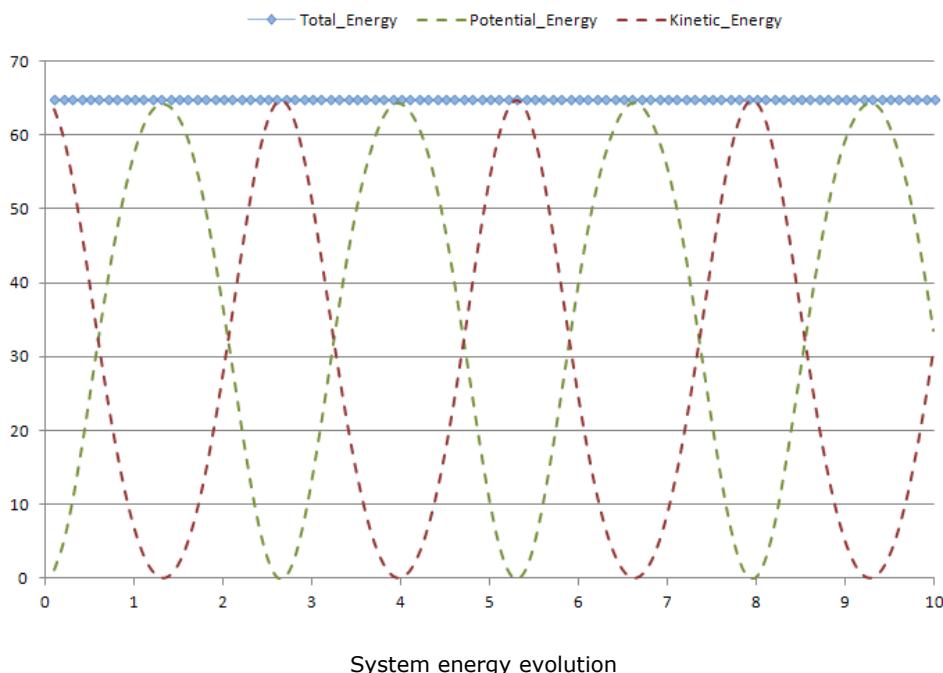

The position of the pendulum in different stages of the analysis is shown in the next image:

Energy conserving results:

The following graphs show the evolution of the pendulum's energy: potential, kinetic, and total. As can be observed, the total energy of the system remains constant:
